Dell t3500 power supply problems

© 1996-2014, Amazon.com, Inc. or its affiliates Hello , I have a PB12 problem with my Dell T3500 . Shows 1 + 2 lights . This generally means a motherboard issue . The oddity here is that this problem arose some time ago and then disappeared , a few weeks ago the front two fans started running at high speed constantly up until yesterday when I decided to shut down instead of sleep/hibernate . I have cleared BIOS and reseated the graphics card / memory (also tried 3 ram sticks / 6 ram and switched them) . During the startup attempt all fans run , front 2 , rear 2 and Graphics card . Now if something on the motherboard broke (usual general consensus is that a PB12 means the MB is dead) , why would it work up until now ? This is the second M/B (the first was replaced by the vendor - well actually swapped the whole computer) that I have had this problem with . Hoping someone has some insights into this problem as a replacement is not available locally , and the shipping expensive . Last edited: May 26, 2018 I just repaired a Dell Precision T3500 a week ago. Same symptoms and it ended up being a bad motherboard. I ordered a good tested one off Ebay and replaced it. Worked just fine afterwards. The board cost around \$40ish. I just repaired a Dell Precision T3500 a week ago. Same symptoms and it ended up being a bad motherboard. I ordered a good tested one off Ebay and replaced it. Worked just fine afterwards. The board cost around \$40ish. Thanks for the reply . THIS sound was a "good tested" (replacement for the previous one that had the same issue) one that was working fine for many months . The board may cost 40ish but the shipping charges will at LEAST double that . Look at the shipping cost of a new board with warranty ! Why would I previously have a PB12 issue (tried many times and resigned to a junk throw away computer) , then suddenly repaired itself and continued for many weeks ? Can anyone explain what has actually ceased to work and why ? When I press the power button the 3 and 4 lights actually flash momentarily . The Dell case is a marvel and made to a high standard , the power supply suitable for long use . But I am more that a little miffed at not one , but two boards failing for exactly the same reason within a relatively short time . It's possible (not for sure) you may have a faulty PSU which is the cause of your problems. I would at least try switching in a different PSU to see if that helps before you assign the motherboard to the garbage bin. EUREKA !! I have recovered from this PB12 error ! I am now sending this post from the same computer that everyone condemned as broken . Sorry for this blatant act of crowing but I have not heard from anyone who has done this . Am I alone in this ? daveybrat I hope you did not throw out your old (considered Useless) motherboard ? I must have tried hundreds of times to get this thing working , and figure out the back-door . EUREKA !! I have recovered from this PB12 error ! I am now sending this post from the same computer that everyone condemned as broken . Sorry for this blatant act of crowing but I have not heard from anyone who has done this . Am I alone in this ? daveybrat I hope you did not throw out your old (considered Useless) motherboard ? I must have tried hundreds of times to get this thing working , press the power button and 1 + 2 lights flash and the power shuts off - Then I see something , and figure out the back-door . Are you going to share your solution? OK . After the session ended , I stupidly put the computer into hibernate (which has been very slow to re-start previously) instead of sleep and it has reverted . Now the thing is If I have , not once but TWICE , been able to recover from what is generally accepted as a terminal problem then it cannot possibly be broken beyond hope . It would have to be said that I am persistent , and Desperate , so I probably spent more time than most would (just how many times would YOU press buttons until you ordered a overpriced s/h replacement ? 10 ? 20 ?) trying to get it to work . Now , AT WILL , I can get the computer to flash not the 1 + 2 front panel lights , but the 3 + 4 , which is the normal starting sequence . The problem is that it then shuts down . Any insights would be appreciated . Has anyone else managed to get a T3500 working after a PB12 error ? The fact that It has recovered twice (3 times , see following post) is indicative that the problem is rectifiable . Last edited: May 29, 2018 OK . Now THIS is REALLY weird ! Last post I made from an Internet cafe , I get home and FIRST attempt I get it working again ! Now am sending from the T3500 . Can anyone come close to an explanation (apart from an act of God) ?? I think I may contact the dealer who sold me the first T3500 (" died " from the exact same problem) and try and buy it back (at a reduced price of course) ! Recoverable is not the same as rectifiable. XavierMace All information available from Dell on this box . The machine starts to start the machine . But all I see is the first line of text of the CD which is the following:ISO/Linux 3.63 2008-04-10 Copyright (C) 1994-2008 h. Peter AvnirMy next thought was that there was something wrong with the ISO image that I downloaded . I tested it on another machine, has worked like a champ . Now, I read on a few different posts within the VMWare communities that some people have had luck with this question and others did not.The inventory number of Dell on the machine is 6HDG81Any advice would be greatly appreciated. Some of the Dell CD-ROM may be little flighty. I had hard time to install a CD earlier which worked perfectly well on another machine. I made another copy of the disc, this time burning the CD at a 4 x speed. The installation went perfectly fine afterwards. Dell XPS-8900 does not start Worked well to date, 01/01/2016 - Happy New Year, NO! Change power cable, use a different outlet (other items such as router and network printer can very well). Computer still does not start. When I plug it in the computer power light turns on light and then turns off (this seemed normal before). So if I push the power button computer does not start. I don't seem to get an orange light sequence of 2-1 after trying to turn it on - and continues. Maybe some sort of signal POST? I can turn the computer (not my first choice) after our journey ahead. But I'd rather get it upward and now running. Have work to do. Phil More information. I had four USB3 external drives attached, whose two propulsion and two disks Seagate Wireless - which is recharged through its USB port. Removing only the second Seagate drive allows the machine starts. So the question can be too much of a drain on the USB card current. Once started, the system seems to work very well with that wireless Seagate drive attached, and it restarts with it attached - just not boot from a condition of Shut Down. Not sure really, I understand that, but I can live with that. If someone seems something more insidious in this behavior, please notify; bought the XPS-8900 at COSTCO and still about 55 days return if it is defective! Phil Dell Precision T5400 will not start, turns off immediately Dell Precision T5400 Xeon E5450 x 2 32 GB of Ram Windows 7 Pro 1 TB Seagate drive primary Backup WD 2 TB drive Rewritable DVD Floppy drive FX Radeon HD 7850 2 GB PCI Firewire card These days it would be closed to chance especially when watching Youtube videos. I've recently updated my driver video so cancelled yesterday. This morning when I woke up, it was off, I let it run all the time so I knew that he was stopped again. I hit the power button, the power came on and stay on, but it's like that. No video appears on the screen. The monitor works but like I said it seems that he stops before the system reached the stage of the bios boot screen. Graphics card is ok tested in another machine from dell.I've deleted all the ram cards and hard drive even the system battery (and reinstalled it) and tried to start but the same result with the fans on and the same facade turns on with the power button on steady green. His market XP Professional SP3 32-bit with 4 GB of ram a dual core Xeon 5160 3 GHz processor and disk of 1 TB sata hard.Any suggestions would be great,Thank youGeorge John, Thank you for your response.I found my problem and currently turning fine. I bought a couple of xeon E5440 processors who don't are not supported by the Council. I had to find it takes 5100 or 5300 series. Once I installed the 5300 series, everything was fine. Thank you for your response. Vince Dell Dimension C521 does not start I have a Dell Dimension C521 desktop computer. When I try to start it, the fan turns on and is really hard, but the screen does not light. The power light on my computer lights up (green), but the 3 & 4 diagnostic lights flash repeatedly on the front of the computer. What is the cause? What can I do about it? Hello Bev, The rest green power light on, no blinking, no beeps. I had no problem until last night after that I removed the hard drive and reinstalled. How can I remove the memory modules? Thanks) NetFanatic123 For the removal and reinstallation of the RAM, details are HERE NOTE from the ADMIN: broken link has been removed from this post by Dell > A hint: make sure that the modules are filled into the slots and the clips are in the notches. While the case is open, check that all the power cable and the data are correctly connected to the drive and the motherboard, by removing and reconnecting them. Why the hard disk has been deleted and reinstalled, was this HD bought a bad CPU, so I can return. Thank you Andrew Hello First of all, I tried to send this last night but received a message on my post approval by moderator? Not yet been approved but seen other people have posted with success more recently. Do not know what is happening. In any case, put his hand on a 3.4 GHz HT P4 Northwood 512 Kb 800 Mhz FSB for E10 on Ebay to upgrade my mother enough old Dimension 4600 which has a 2.8 Ghz P4 512 KB 533 FSB inside... However, when I install it the computer does not light and shows just a light amber. The readers and fans still spin but there is no display. The computer works normally when I put the old one back in. I think somehow it is a power supply problem as the new processor uses 20w more energy than the old 2.8 Ghz one. Someone at - it ideas? Just trying to figure if I bought a bad CPU, so I can return. Thank you Andrew Hello First of all, I tried to send this last night but received a message on my post approval by moderator? Not yet been approved but seen other people have posted with success more recently. Do not know what is happening. In any case, put his hand on a 3.4 GHz HT P4 Northwood 512 Kb 800 Mhz FSB for E10 on Ebay to upgrade my mother enough old Dimension 4600 which has a 2.8 Ghz P4 512 Kb 533 FSB inside... However, when I install it the computer does not light and shows just a light amber. The readers and fans still spin but there is no display. The computer works normally when I put the old one back in. I think somehow it is a power supply problem as the new processor uses 20w more energy than the old 2.8 Ghz one. Someone at - it ideas? Just trying to figure if I bought a bad CPU, so I can return. Thank you Andrew AV115 Andrew, It is not a power supply problem, it's incompatible, or a bad processor problem. The first models of 4600 will take up to 3.0 GHz and models later, 3.2 GHz to 3.4 GHz, but this does not offer much of a sudden boost on the 3.0 GHz Motherboard Dell P/N F4491 will support up to 3.4 Ghz Northwood leaving Prescott Bev. Dell Studio 540MT does not start, green power light on, but the Start button / clear stop completely Looking for assistance Have a Dell Studio 540MT (purchased in 2009), worked great until 2 weeks ago . After a temporary system failure would not start . The power light itself is green fixed. The power button on the front panel is completely released. I read a lot of messages and other information about a similar problem. Therefore, I did following: 1. unplug everything, press the power button / stop for 1 minute and retries . without success 2. replace the CMOS battery . without success 3A jumps the Green and black 20 supply connection wire pins to motherboard. It started immediately food, fans and hard drive . so I assumed that the PSU has been authorized. 4 replace the motherboard with a new mobo. Curiously, in a first time, there was no change, but after about 2 minutes, the power button was working and power system. Everything worked so very well. I had also completely cleaned all the dust in the chassis and radiator, fan and had applied the thermal paster as directed by Artic Silver . I even turned off after hours of race and restarted system. Restarted, he noted that it took a couple times by pressing the power button to make it work . Then the 2nd day I shut down the system by a normal shutdown through Win 7 and let rest for about 10 hours . When tried to start/turning the power on again, same problem as the original problem..., at first, before light power button would show amber flashing when first pressed the power button / stop, then once I unplugged the power cord and let it sit for 1 hour, the light power button showed no light, completely and again no restarts. 5. I ordered a new power button cord (new)... This could be the problem and replacement will fix? Is this a known problem that power button can cause this kind of problem? 6 or is a problem of power supply? But you wonder why the green light of the PSU and works very well when jumping the Green and black wire on the connector 20 pin? Before I go buy a new power supply to other suggestions? Is there a known issue with button / stop itself and/or PSU on Dell Studio 540 MTs? Yes, the front panel can cause failure to start in some models, although I don't specifically remember if the 540 has been affected by this problem. Please let me know if the replacement resolves the problem. ATX power supplies should work. Here are the standard components of the Dell desktop computers. Dell XPS 8500 does not start after the interruption of system restore It was one thing to do, but I turned off my PC during the restoration of the system because he took time to complete the process. The next day I couldn't boot into windows. I tried the automatic repair feature, but it does not work. I tried to repair windows using the original installation disk, but it does not work. I tried to install Windows 8 all over again, but I got an error message - media pilot is missing. I opened the box uninstall the RAM, videocard unplugged and both drives and reinstall, but without success. I noticed that there is an orange/orange light on the motherboard. I thought it was the hard drive at the beginning, but now I hope that this is not the motherboard. Any help will be appreciated. RB You have damaged the image beyond repair. You need to reinstall from scratch. Windows to say that an optical drive driver is missing, bad copy of DVD-RW, DVD + R or DVD - R media that was not burned at 1 X 2 X or 4 X, so is not readable. This is why USB Flash Drive 16 GB or more is recommended rather than the DVD player to the installation media. Why doesn't my CD or DVD drive? Troubleshoot installation of Windows 7 Service Pack 1 A required CD/DVD drive device driver is missingA media computer driver needs is missingerror message when you install Windows This problem occurs for the following reasons: The installation DVD is removed during the installation process.A bad quality DVD has been used to create the installation DVD.The speed at which the installation DVD is burnt was too fast.The DVD record cannot read media.The ISO file is corrupted.My Dell Precision 370 computer not start Windows XP, due to A MISSING or CORRUPT FILE. The file that is missing, is a Windows root folder called > System32\hal.dll Since this computer Dell was bought for our children used to use, I don't have any Windows XP disk to install the missing file of root or reinstall Windows XP software. So, how can I get this missing windows xp root file, in order to exploit the windows xp software? I tried to re - start the dell computer, but nothing works! If someone could help me, I would appreciate it a lot. Is it extremely unlikely that the hal.dll file is really missing or damaged. It is extremely likely that XP can't find it either because the file system is afflicted or XP is told to find the file in the right place. Please provide additional information on your system: What is your system brand and model? What is your Version of XP and the Service Pack? Describe your current antivirus and software anti malware situation: McAfee, Symantec, Norton, Spybot, AVG, Avira!, MSE, Panda, Trend Micro, CA, Defender, ZoneAlarm, PC Tools, Comodo, etc.. The question was preceded by a loss of power, aborted reboot or abnormal termination? (this includes the plug pulling, buttons power, remove the battery, etc.) The afflicted system has a CD/DVD drive work? If the system works, what do you think might have changed since the last time it did not work properly? We should first check the integrity of your file system and then see what then to do. Use the XP Recovery Console to check the file system on your HARD drive and fix the problems and then try to start your system - this may be all you need to do. Or, you are welcome to just start trying things that might work. Boot into the Recovery Console Windows using an XP bootable installation CD. If you have no XP bootable media (or aren't sure you have) create a bootable XP Recovery CD of Console and do not forget. This is not the same as recovery disks that may have come to a store to purchase the system. You can make a bootable Recovery Console CD by downloading an ISO file and burn it to a CD. The ISO bootable image file you need to download is called: xp_rec_console.ISO Download the ISO from here: Use a new CD and this simple and free program to burn your ISO file and create your bootable CD: Here are some instructions for ImgBurn: It would be a good idea to test your bootable CD on a computer running. You may need to adjust the computer BIOS settings to use the CD-ROM drive as the first device to boot instead of the hard drive. These adjustments are made before Windows tries to load. If you miss it, you will need to restart the system again. When you start on the CD, follow the instructions: Press any key to boot from CD... Installing Windows... going to announce. Press 'R' to enter the Recovery Console. Select the installation that you want to access (usually 1: C:\WINDOWS) You may be asked to enter the password (usually empty). You should be in the folder C:\WINDOWS. It's the same as the C:\Windows folder that you see in Solution Explorer. The Recovery Console allows base as file commands: copy, rename, replace, delete, chkdsk, fixboot, fixmbr, cd, etc. For a list of the commands in the Recovery Console, type help at the prompt of commands or read on here XP Recovery Console: good idea before you start things must first verify the integrity of your file system by using the chkdsk command. In the command prompt window, run the chkdsk command on the drive where Windows is installed to try to fix any problems on the afflicted player. Running chkdsk is fine, even if he finds no problem. It won't hurt anything to run it. Assuming your boot drive is C, run the following command: CHKDSK C: /r Let chkdsk finish to correct the problems, he could find. It may take a long time for chkdsk complete or they seem to be "stuck". Be patient. If the HARD drive led links always, chkdsk is something. Keep an eye on the amount of the percentage to be sure that it is still making progress. It may even seem to go back sometime. You must run chkdsk/r again until it finds no error to correct.Remove the CD, and then type "exit" to exit the RC and restart the computer. You have not to set the BIOS to boot the disk HARD since the CD won't be.
